Accessing Databases with JDBC

It is a capital mistake to theorize before one has data.
—Arthur Conan Doyle

Now go, write it before them in a table, and note it in a book, that it may be for the time to come for ever and ever.
—The Holy Bible, Isaiah 30:8

Get your facts first, and then you can distort them as much as you please.
—Mark Twain

I like two kinds of men: domestic and foreign.
—Mae West

Objectives
In this chapter you’ll learn:

■ Relational database concepts.
■ To use Structured Query Language (SQL) to retrieve data from and manipulate data in a database.
■ To use the JDBC™ API to access databases.
■ To use the RowSet interface to manipulate databases.
■ To use JDBC 4.0’s automatic JDBC driver discovery.
■ To use PreparedStatements to create precompiled SQL statements with parameters.
■ How transaction processing makes database applications more robust.
Chapter 28 Accessing Databases with JDBC

28.1 Introduction
A database is an organized collection of data. There are many different strategies for organizing data to facilitate easy access and manipulation. A database management system (DBMS) provides mechanisms for storing, organizing, retrieving and modifying data for many users. Database management systems allow for the access and storage of data without concern for the internal representation of data.

Today’s most popular database systems are relational databases, where the data is stored without consideration of its physical structure (Section 28.2). A language called SQL—pronounced “sequel,” or as its individual letters—is the international standard language used almost universally with relational databases to perform queries (i.e., to request information that satisfies given criteria) and to manipulate data. [Note: As you learn about SQL, you’ll see some authors writing “a SQL statement” (which assumes the pronunciation “sequel”) and others writing “an SQL statement” (which assumes that the individual letters are pronounced). In this book we pronounce SQL as “sequel.”]

Some popular relational database management systems (RDBMSs) are Microsoft SQL Server, Oracle, Sybase, IBM DB2, Informix, PostgreSQL and MySQL. The JDK now comes with a pure-Java RDBMS called Java DB—Sun’s version of Apache Derby. In this chapter, we present examples using MySQL and Java DB.

Java programs communicate with databases and manipulate their data using the Java Database Connectivity (JDBC™) API. A JDBC driver enables Java applications to connect to a database in a particular DBMS and allows you to manipulate that database using the JDBC API.

Software Engineering Observation 28.1
Using the JDBC API enables developers to change the underlying DBMS without modifying the Java code that accesses the database.
Most popular database management systems now provide JDBC drivers. There are also many third-party JDBC drivers available. In this chapter, we introduce JDBC and use it to manipulate MySQL and Java DB databases. The techniques demonstrated here can also be used to manipulate other databases that have JDBC drivers. Check your DBMS’s documentation to determine whether your DBMS comes with a JDBC driver. If not, third-party vendors provide JDBC drivers for many DBMSs.

**Software Engineering Observation 28.2**
Most major database vendors provide their own JDBC database drivers, and many third-party vendors provide JDBC drivers as well. For more information visit devapp.sun.com/product/jdbc/drivers.

For more information on JDBC, visit java.sun.com/javase/technologies/database/index.jsp which contains JDBC information including the JDBC specification, FAQs, a learning resource center and software downloads to search for JDBC drivers for your DBMS, and developers.sun.com/product/jdbc/drivers/ which provides a search engine to help you locate drivers appropriate for your DBMS.

### 28.2 Relational Databases

A **relational database** is a logical representation of data that allows the data to be accessed without consideration of its physical structure. A relational database stores data in **tables**. Figure 28.1 illustrates a sample table that might be used in a personnel system. The table name is **Employee**, and its primary purpose is to store the attributes of an employee. Tables are composed of **rows**, and rows are composed of **columns** in which values are stored. This table consists of six rows. The **Number** column of each row is the table’s **primary key**—a column (or group of columns) with a unique value that cannot be duplicated in other rows. This guarantees that each row can be identified by its primary key. Good examples of primary key columns are a social security number, an employee ID number and a part number in an inventory system, as values in each of these columns are guaranteed to be unique. The rows in Fig. 28.1 are displayed in order by primary key. In this case, the rows are listed in increasing order, but we could also use decreasing order.

![Figure 28.1 Employee table sample data.](image-url)

Chapter 28   Accessing Databases with JDBC

Rows in tables are not guaranteed to be stored in any particular order. As we'll demonstrate in an upcoming example, programs can specify ordering criteria when requesting data from a database.

Each column represents a different data attribute. Rows are normally unique (by primary key) within a table, but particular column values may be duplicated between rows. For example, three different rows in the Employee table's Department column contain number 413.

Different users of a database are often interested in different data and different relationships among the data. Most users require only subsets of the rows and columns. To obtain these subsets, you use queries to specify which data to select from a table. You use SQL to define complex queries. For example, you might select data from the Employee table to create a result that shows where each department is located, presenting the data sorted in increasing order by department number. This result is shown in Fig. 28.2. SQL queries are discussed in Section 28.4.

28.3 Relational Database Overview: The books Database

We now overview relational databases in the context of a sample books database we created for this chapter. Before we discuss SQL, we discuss the tables of the books database. We use this database to introduce various database concepts, including how to use SQL to obtain information from the database and to manipulate the data. We provide a script to create the database. You can find the script in the examples directory for this chapter. Section 28.7 explains how to use this script.

The database consists of three tables: Authors, AuthorISBN and Titles. The Authors table (described in Fig. 28.3) consists of three columns that maintain each author’s unique ID number, first name and last name. Figure 28.4 contains sample data from the Authors table of the books database.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuthorID</td>
<td>Author's ID number in the database. In the books database, this integer column is defined as autoincremented—for each row inserted in this table, the AuthorID value is increased by 1 automatically to ensure that each row has a unique AuthorID. This column represents the table's primary key.</td>
</tr>
<tr>
<td>FirstName</td>
<td>Author's first name (a string).</td>
</tr>
<tr>
<td>LastName</td>
<td>Author's last name (a string).</td>
</tr>
</tbody>
</table>

<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>413</td>
<td>New Jersey</td>
</tr>
<tr>
<td>611</td>
<td>Orlando</td>
</tr>
<tr>
<td>642</td>
<td>Los Angeles</td>
</tr>
</tbody>
</table>

Fig. 28.3   | Authors table from the books database.

28.3 Relational Database Overview: The books Database

The AuthorISBN table (described in Fig. 28.5) consists of two columns that maintain each ISBN and the corresponding author’s ID number. This table associates authors with their books. Both columns are foreign keys that represent the relationship between the tables Authors and Titles—one row in table Authors may be associated with many rows in table Titles, and vice versa. The combined columns of the AuthorISBN table represent the table’s primary key—thus, each row in this table must be a unique combination of an AuthorID and an ISBN. Figure 28.6 contains sample data from the AuthorISBN table of the books database. [Note: To save space, we have split the contents of this table into two columns, each containing the AuthorID and ISBN columns.] The AuthorID column is a foreign key—a column in this table that matches the primary key column in another table (i.e., AuthorID in the Authors table). Foreign keys are specified when creating a table. The foreign key helps maintain the Rule of Referential Integrity—every foreign-key value must appear as another table’s primary-key value. This enables the DBMS to determine whether the AuthorID value for a particular book is valid. Foreign keys also allow related data in multiple tables to be selected from those tables for analytic purposes—this is known as joining the data.

The Titles table described in Fig. 28.7 consists of four columns that stand for the ISBN, the title, the edition number and the copyright year. The table is in Fig. 28.8.
Chapter 28  Accessing Databases with JDBC

There is a one-to-many relationship between a primary key and a corresponding foreign key (e.g., one publisher can publish many books). A foreign key can appear many times in its own table, but can appear only once (as the primary key) in another table. Figure 28.9 is an entity-relationship (ER) diagram for the books database. This diagram shows the database tables and the relationships among them. The first compartment in each box contains the table’s name and the remaining compartments contain the table’s columns. The names in italic are primary keys. A table’s primary key uniquely identifies each row in the table. Every row must have a primary-key value, and that value must be unique in the table. This is known as the Rule of Entity Integrity. Again, for the Author-ISBN table, the primary key is the combination of both columns.

<table>

</tr>
</tbody>
</table>

**Fig. 28.8**  | Sample data from the Titles table of the books database.

The table relationships in the books database.
The lines connecting the tables (Fig. 28.9) represent the relationships between the tables. Consider the line between the AuthorISBN and Authors tables. On the Authors end of the line is a 1, and on the AuthorISBN end is an infinity symbol (∞), indicating a one-to-many relationship in which every author in the Authors table can have an arbitrary number of books in the AuthorISBN table. The relationship line links the AuthorID column in Authors (i.e., its primary key) to the AuthorID column in AuthorISBN (i.e., its foreign key). The AuthorID column in the AuthorISBN table is a foreign key.

The line between Titles and AuthorISBN illustrates another one-to-many relationship; a title can be written by any number of authors. In fact, the sole purpose of the AuthorISBN table is to provide a many-to-many relationship between Authors and Titles—an author can write many books and a book can have many authors.

28.4 SQL

We now provide an overview of SQL in the context of our books database. You’ll be able to use the SQL discussed here in the examples later in the chapter and in examples in Chapters 30–31.

The next several subsections discuss the SQL keywords listed in Fig. 28.10 in the context of SQL queries and statements. Other SQL keywords are beyond this text’s scope. To learn other keywords, refer to the SQL reference guide supplied by the vendor of the RDBMS you are using. [Note: For more information on SQL, refer to the web resources in Section 28.15.]

<table>
<thead>
<tr>

<td>Criteria for ordering rows. Optional in a SELECT query.</td>
</tr>
</tbody>
</table>

Fig. 28.10 | SQL query keywords. (Part 1 of 2.)
Chapter 28  Accessing Databases with JDBC

28.4.1 Basic SELECT Query

Let us consider several SQL queries that extract information from database books. A SQL query "selects" rows and columns from one or more tables in a database. Such selections are performed by queries with the SELECT keyword. The basic form of a SELECT query is

```
SELECT * FROM tableName
```

in which the asterisk (*) wildcard character indicates that all columns from the tableName table should be retrieved. For example, to retrieve all the data in the Authors table, use

```
SELECT * FROM Authors
```

Most programs do not require all the data in a table. To retrieve only specific columns, replace the asterisk (*) with a comma-separated list of the column names. For example, to retrieve only the columns AuthorID and LastName for all rows in the Authors table, use the query

```
SELECT AuthorID, LastName FROM Authors
```

This query returns the data listed in Fig. 28.11.

<table>
<thead>
<tr>
<th>AuthorID</th>
<th>LastName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Deitel</td>
</tr>
<tr>
<td>2</td>
<td>Deitel</td>
</tr>
<tr>
<td>3</td>
<td>Goldberg</td>
</tr>
<tr>
<td>4</td>
<td>Choffnes</td>
</tr>
</tbody>
</table>

Fig. 28.11 | Sample AuthorID and LastName data from the Authors table.

Software Engineering Observation 28.3

For most queries, the asterisk (*) should not be used to specify column names. In general, you process results by knowing in advance the order of the columns in the results—for example, selecting AuthorID and LastName from table Authors ensures that the columns will appear in the result with AuthorID as the first column and LastName as the second column. Programs typically process result columns by specifying the column number in the result (starting from number 1 for the first column). Selecting columns by name also avoids returning unneeded columns and protects against changes in the actual order of the columns in the table(s) by returning the columns in the exact order specified.
28.4.2 WHERE Clause

In most cases, it is necessary to locate rows in a database that satisfy certain selection criteria. Only rows that satisfy the selection criteria (formally called predicates) are selected. SQL uses the optional **WHERE clause** in a query to specify the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ...
FROM tableName
WHERE criteria
```

For example, to select the Title, EditionNumber and Copyright columns from table Titles for which the Copyright date is greater than 2005, use the query

```
SELECT Title, EditionNumber, Copyright
FROM Titles
WHERE Copyright > '2005'
```

Notice that strings in SQL are delimited by single (') rather than double (") quotes.

Figure 28.12 shows the result of the preceding query. The **WHERE clause** criteria can contain the operators <, >, <=, >=, =, <> and LIKE. Operator **LIKE** is used for **pattern matching** with wildcard characters percent (%) and underscore (_). Pattern matching allows SQL to search for strings that match a given pattern.

<table>
<thead>
<tr>
<th>Title</th>
<th>EditionNumber</th>
<th>Copyright</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visual C# 2005 How to Program</td>
<td>2</td>
<td>2006</td>
</tr>
<tr>
<td>Visual Basic 2005 How to Program</td>
<td>3</td>
<td>2006</td>
</tr>
<tr>
<td>Java How to Program</td>
<td>7</td>
<td>2007</td>
</tr>
<tr>
<td>C How to Program</td>
<td>5</td>
<td>2007</td>
</tr>
</tbody>
</table>

**Fig. 28.12** | Sampling of titles with copyrights after 2005 from table Titles.

A pattern that contains a percent character (%) searches for strings that have zero or more characters at the percent character’s position in the pattern. For example, the next query locates the rows of all the authors whose last name starts with the letter D:

```
SELECT AuthorID, FirstName, LastName
FROM Authors
WHERE LastName LIKE 'D%'
```

This query selects the two rows shown in Fig. 28.13—two of the four authors have a last name starting with the letter D (followed by zero or more characters). The % symbol in the **WHERE clause**’s LIKE pattern indicates that any number of characters can appear after the letter D in the **LastName**. Note that the pattern string is surrounded by single-quote characters.
Chapter 28  Accessing Databases with JDBC

An underscore (\_) in the pattern string indicates a single wildcard character at that position in the pattern. For example, the following query locates the rows of all the authors whose last names start with any character (specified by \_), followed by the letter o, followed by any number of additional characters (specified by %):

\[
\text{SELECT AuthorID, FirstName, LastName}
\text{FROM Authors}
\text{WHERE LastName LIKE '_o%'}
\]

The preceding query produces the row shown in Fig. 28.14, because only one author in our database has a last name that contains the letter o as its second letter.

Portability Tip 28.1  
See the documentation for your database system to determine whether SQL is case sensitive on your system and to determine the syntax for SQL keywords (i.e., should they be all uppercase letters, all lowercase letters or some combination of the two?).

Portability Tip 28.2  
Read your database system’s documentation carefully to determine whether it supports the LIKE operator as discussed here. The SQL we discuss is supported by most RDBMSs, but it is always a good idea to check the features of SQL that are supported by your RDBMS.

28.4.3 ORDER BY Clause

The rows in the result of a query can be sorted into ascending or descending order by using the optional ORDER BY clause. The basic form of a query with an ORDER BY clause is

\[
\text{SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC}
\]

where ASC specifies ascending order (lowest to highest), DESC specifies descending order (highest to lowest) and columnName specifies the column on which the sort is based. For example, to obtain the list of authors in ascending order by last name (Fig. 28.15), use the query

\[
\text{SELECT AuthorID, FirstName, LastName}
\text{FROM Authors}
\text{ORDER BY LastName ASC}
\]
Note that the default sorting order is ascending, so ASC is optional. To obtain the same list of authors in descending order by last name (Fig. 28.16), use the query

\[
\begin{align*}
\text{SELECT} & \quad \text{AuthorID, FirstName, LastName} \\
\text{FROM} & \quad \text{Authors} \\
\text{ORDER BY} & \quad \text{LastName DESC}
\end{align*}
\]

Multiple columns can be used for sorting with an ORDER BY clause of the form

\[
\text{ORDER BY column1 sortingOrder, column2 sortingOrder, ...}
\]

where \text{sortingOrder} is either ASC or DESC. Note that the \text{sortingOrder} does not have to be identical for each column. The query

\[
\begin{align*}
\text{SELECT} & \quad \text{AuthorID, FirstName, LastName} \\
\text{FROM} & \quad \text{Authors} \\
\text{ORDER BY} & \quad \text{LastName, FirstName}
\end{align*}
\]

sorts all the rows in ascending order by last name, then by first name. If any rows have the same last-name value, they're returned sorted by first name (Fig. 28.17).
Chapter 28 Accessing Databases with JDBC

The WHERE and ORDER BY clauses can be combined in one query, as in

```sql
SELECT ISBN, Title, EditionNumber, Copyright
FROM Titles
WHERE Title LIKE '%How to Program'
ORDER BY Title ASC
```

which returns the ISBN, Title, EditionNumber and Copyright of each book in the Titles table that has a Title ending with "How to Program" and sorts them in ascending order by Title. The query results are shown in Fig. 28.18.

<table>

### 28.4.4 Merging Data from Multiple Tables: INNER JOIN

Database designers often split related data into separate tables to ensure that a database does not store data redundantly. For example, the books database has tables Authors and Titles. We use an AuthorISBN table to store the relationship data between authors and their corresponding titles. If we did not separate this information into individual tables, we would need to include author information with each entry in the Titles table. This would result in the database's storing duplicate author information for authors who wrote multiple books. Often, it is necessary to merge data from multiple tables into a single result. Referred to as joining the tables, this is specified by an INNER JOIN operator in the query. An INNER JOIN merges rows from two tables by matching values in columns that are common to the tables. The basic form of an INNER JOIN is:

```sql
SELECT columnName1, columnName2, ...
FROM table1
INNER JOIN table2 ON table1.columnName = table2.columnName
```

The **ON clause** of the INNER JOIN specifies the columns from each table that are compared to determine which rows are merged. For example, the following query produces a list of authors accompanied by the ISBNs for books written by each author:

```sql
SELECT FirstName, LastName, ISBN
FROM Authors
INNER JOIN AuthorISBN ON Authors.AuthorID = AuthorISBN.AuthorID
ORDER BY LastName, FirstName
```

The query merges the FirstName and LastName columns from table Authors with the ISBN column from table AuthorISBN, sorting the result in ascending order by LastName and FirstName. Note the use of the syntax tableName.columnName in the ON clause. This syntax, called a qualified name, specifies the columns from each table that should be compared to join the tables. The “tableName.” syntax is required if the columns have the same name in both tables. The same syntax can be used in any SQL statement to distinguish columns in different tables that have the same name. In some systems, table names qualified with the database name can be used to perform cross-database queries. As always, the query can contain an ORDER BY clause. Figure 28.19 shows the results of the preceding query, ordered by LastName and FirstName. [Note: To save space, we split the result of the query into two columns, each containing the FirstName, LastName and ISBN columns.]

<table>

<td>Andrew</td>
<td>Goldberg</td>
<td>0131450913</td>
</tr>
</tbody>
</table>

Fig. 28.19 | Sampling of authors and ISBNs for the books they have written in ascending order by LastName and FirstName.

Software Engineering Observation 28.4
If a SQL statement includes columns with the same name from multiple tables, the statement must precede those column names with their table names and a dot (e.g., Authors.AuthorID).

Common Programming Error 28.5
Failure to qualify names for columns that have the same name in two or more tables is an error.

28.4.5 INSERT Statement
The INSERT statement inserts a row into a table. The basic form of this statement is

```
INSERT INTO tableName (columnName1, columnName2, ..., columnNameN) VALUES (value1, value2, ..., valueN)
```

where tableName is the table in which to insert the row. The tableName is followed by a comma-separated list of column names in parentheses (this list is not required if the INSERT operation specifies a value for every column of the table in the correct order). The list of column names is followed by the SQL keyword VALUES and a comma-separated list of values in parentheses. The values specified here must match the columns specified after the table name in both order and type (e.g., if columnName1 is supposed to be the FirstName
column, then value1 should be a string in single quotes representing the first name). Always explicitly list the columns when inserting rows. If the table’s column order changes or a new column is added, using only VALUES may cause an error. The INSERT statement inserts a row into the Authors table. The statement indicates that values are provided for the FirstName and LastName columns. The corresponding values are ‘Sue’ and ‘Smith’. We do not specify an AuthorID in this example because AuthorID is an autoincremented column in the Authors table. For every row added to this table, the DBMS assigns a unique AuthorID value that is the next value in the autoincremented sequence (i.e., 1, 2, 3 and so on). In this case, Sue Smith would be assigned AuthorID number 5. Figure 28.20 shows the Authors table after the INSERT operation. [Note: Not every database management system supports autoincremented columns. Check the documentation for your DBMS for alternatives to autoincremented columns.]

<table>
<thead>
<tr>
<th>AuthorID</th>
<th>FirstName</th>
<th>LastName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Harvey</td>
<td>Deitel</td>
</tr>
<tr>
<td>2</td>
<td>Paul</td>
<td>Deitel</td>
</tr>
<tr>
<td>3</td>
<td>Andrew</td>
<td>Goldberg</td>
</tr>
<tr>
<td>4</td>
<td>David</td>
<td>Choffnes</td>
</tr>
<tr>
<td>5</td>
<td>Sue</td>
<td>Smith</td>
</tr>
</tbody>
</table>

Fig. 28.20 Sample data from table Authors after an INSERT operation.

**Common Programming Error 28.6**
It is normally an error to specify a value for an autoincrement column.

**Common Programming Error 28.7**
SQL delimits strings with single quotes (‘). A string containing a single quote (e.g., O’Malley) must have two single quotes in the position where the single quote appears (e.g., ‘O’’Malley’). The first acts as an escape character for the second. Not escaping single-quote characters in a string that is part of a SQL statement is a SQL syntax error.

### 28.4.6 UPDATE Statement
An UPDATE statement modifies data in a table. Its basic form is

```
UPDATE tableName
SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
WHERE criteria
```

where `tableName` is the table to update. The `tableName` is followed by keyword `SET` and a comma-separated list of column name/value pairs in the format `columnName = value`. The optional WHERE clause provides criteria that determine which rows to update. Though not required, the WHERE clause is typically used, unless a change is to be made to every row. The UPDATE statement
28.4 SQL

**UPDATE** Authors

SET LastName = 'Jones'

WHERE LastName = 'Smith' AND FirstName = 'Sue'

updates a row in the Authors table. The statement indicates that LastName will be assigned the value Jones for the row in which LastName is equal to Smith and FirstName is equal to Sue. [Note: If there are multiple rows with the first name “Sue” and the last name “Smith,” this statement will modify all such rows to have the last name “Jones.”] If we know the AuthorID in advance of the UPDATE operation (possibly because we searched for it previously), the WHERE clause can be simplified as follows:

WHERE AuthorID = 5

Figure 28.21 shows the Authors table after the UPDATE operation has taken place.

<table>
<thead>
<tr>
<th>AuthorID</th>
<th>FirstName</th>
<th>LastName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Harvey</td>
<td>Deitel</td>

<td>David</td>
<td>Choffnes</td>
</tr>
<tr>
<td>5</td>
<td>Sue</td>
<td>Jones</td>
</tr>
</tbody>
</table>

**Fig. 28.21 | Sample data from table Authors after an UPDATE operation.**

28.4.7 DELETE Statement

A SQL DELETE statement removes rows from a table. Its basic form is

DELETE FROM tableName WHERE criteria

where tableName is the table from which to delete. The optional WHERE clause specifies the criteria used to determine which rows to delete. If this clause is omitted, all the table’s rows are deleted. The DELETE statement

DELETE FROM Authors

WHERE LastName = 'Jones' AND FirstName = 'Sue'

deletes the row for Sue Jones in the Authors table. If we know the AuthorID in advance of the DELETE operation, the WHERE clause can be simplified as follows:

WHERE AuthorID = 5

Figure 28.22 shows the Authors table after the DELETE operation has taken place.

<table>
<thead>
<tr>
<th>AuthorID</th>
<th>FirstName</th>
<th>LastName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Harvey</td>
<td>Deitel</td>
</tr>
<tr>
<td>2</td>
<td>Paul</td>
<td>Deitel</td>
</tr>
<tr>
<td>3</td>
<td>Andrew</td>
<td>Goldberg</td>
</tr>
<tr>
<td>4</td>
<td>David</td>
<td>Choffnes</td>
</tr>
</tbody>
</table>

**Fig. 28.22 | Sample data from table Authors after a DELETE operation.**

28.5 Instructions for Installing MySQL and MySQL Connector/J

MySQL 5.0 Community Edition is an open-source database management system that executes on many platforms, including Windows, Solaris, Linux, and Macintosh. Complete information about MySQL is available from www.mysql.com. The examples in Sections 28.8—28.9 manipulate MySQL databases.

**Installing MySQL**

To install MySQL Community Edition:

1. To learn about the installation requirements for your platform, visit the site dev.mysql.com/doc/refman/5.0/en/installing-cs.html.
2. Visit dev.mysql.com/downloads/mysql/5.0.html and download the installer for your platform. For the MySQL examples in this chapter, you need only the Windows Essentials package on Microsoft Windows, or the Standard package on most other platforms. [Note: For these instructions, we assume you are running Microsoft Windows. Complete installation instructions for other platforms are available at dev.mysql.com/doc/refman/5.0/en/installing.html.]
3. Double click mysql-essential-5.0.67-win32.msi to start the installer. [Note: This name may differ based on the current version of MySQL 5.0.] Click Next >.
4. Choose Typical for the Setup Type and click Next >. Then click Install.

When the installation completes, click Next > twice, then Finish to begin configuring the server. To configure the server:

1. Click Next >, then select Standard Configuration and click Next > again.
2. You have the option of installing MySQL as a Windows service, which enables the MySQL server to begin executing automatically each time your system starts. For our examples, this is unnecessary, so uncheck Install as a Windows Service, then check Include Bin Directory in Windows PATH. This will enable you to use the MySQL commands in the Windows Command Prompt.
3. Click Next >, then click Execute to perform the server configuration.
4. Click Finish to close the wizard.

**Installing MySQL Connector/J**

To use MySQL with JDBC, you also need to install MySQL Connector/J (the J stands for Java)—a JDBC driver that allows programs to use JDBC to interact with MySQL. MySQL Connector/J can be downloaded from dev.mysql.com/downloads/connector/j/5.1.html.

The documentation for Connector/J is located at dev.mysql.com/doc/connector/j/en/connector-j.html. At the time of this writing, the current generally available release of MySQL Connector/J is 5.1.7. To install MySQL Connector/J:

1. Download mysql-connector-java-5.1.7.tar.gz.
2. Open mysql-connector-java-5.1.7.tar.gz with a file extractor, such as WinZip (www.winzip.com). Extract its contents to the C:\ drive. This will create a directory named mysql-connector-java-5.1.7. This folder's docs subdirectory © 2010 Pearson Education, Inc., Upper Saddle River, NJ. All Rights Reserved.
28.6 Instructions for Setting Up a MySQL User Account

For the MySQL examples to execute correctly, you need to set up a user account that allows users to create, delete and modify a database. After MySQL is installed, follow the steps below to set up a user account (these steps assume MySQL is installed in its default installation directory):

1. Open a Command Prompt and start the database server by executing the command `mysqld-nt.exe`. Note that this command has no output—it simply starts the MySQL server. Do not close this window—doing so terminates the server.

2. Next, you’ll start the MySQL monitor so you can set up a user account, open another Command Prompt and execute the command:

   ```bash
   mysql -h localhost -u root
   ```

   The `-h` option indicates the host (i.e., computer) on which the MySQL server is running—in this case your local computer (`localhost`). The `-u` option indicates the user account that will be used to log in to the server—`root` is the default user account that is created during installation to allow you to configure the server. Once you’ve logged in, you’ll see a `mysql>` prompt at which you can type commands to interact with the MySQL server.

3. At the `mysql>` prompt, type:

   ```sql
   USE mysql;
   ```

   to select the built-in database named `mysql`, which stores server information, such as user accounts and their privileges for interacting with the server. Note that each command must end with a semicolon. To confirm the command, MySQL issues the message "Database changed."

4. Next, you’ll add the `deitel` user account to the `mysql` built-in database. The `mysql` database contains a table called `user` with columns that represent the user’s name, password and various privileges. To create the `deitel` user account with the password `deitel`, execute the following commands from the `mysql>` prompt:

   ```sql
   create user 'deitel'@'localhost' identified by 'deitel';
   grant select, insert, update, delete, create, drop, references, execute on *.* to 'deitel'@'localhost';
   ```

   This creates the `deitel` user with the privileges needed to create the databases used in this chapter and manipulate them.

5. Type the command

   ```bash
   exit;
   ```

   to terminate the MySQL monitor.

28.7 Creating Database books in MySQL

For each MySQL database we discuss, we provide a SQL script in a `.sql` file that sets up the database and its tables. You can execute these scripts in the MySQL monitor. In this
chapter’s examples directory, you’ll find the script books.sql to create the books database. For the following steps, we assume that the MySQL server (mysqld-nt.exe) is still running. To execute the books.sql script:

1. Open a Command Prompt and use the cd command to change directories to the location that contains the books.sql script.
2. Start the MySQL monitor by typing
   ```
   mysql -h localhost -u deitel -p
   ```
   The -p option prompts you for the password for the deitel user account. When prompted, enter the password deitel.
3. Execute the script by typing
   ```
   source books.sql;
   ```
   This creates a new directory named books in the server’s data directory—located by default on Windows at C:\Program Files\MySQL\MySQL Server 5.0\data. This new directory contains the books database.
4. Type the command
   ```
   exit;
   ```
   to terminate the MySQL monitor. You are now ready to proceed to the first JDBC example.

### 28.8 Manipulating Databases with JDBC

In this section, we present two examples. The first introduces how to connect to a database and query the database. The second demonstrates how to display the result of the query in a JTable.

#### 28.8.1 Connecting to and Querying a Database

The example of Fig. 28.23 performs a simple query on the books database that retrieves the entire Authors table and displays the data. The program illustrates connecting to the database, querying the database and processing the result. The discussion that follows presents the key JDBC aspects of the program. ([Note: Sections 28.5—28.7 demonstrate how to start the MySQL server, configure a user account and create the books database. These steps must be performed before executing the program of Fig. 28.23.])

```java
// Fig. 28.23: DisplayAuthors.java
// Displaying the contents of the Authors table.
import java.sql.Connection;
import java.sql.Statement;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.ResultSetMetaData;
import java.sql.SQLException;
```

---

**Fig. 28.23** | Displaying the contents of the Authors table. (Part 1 of 3.)

public class DisplayAuthors
{
    // database URL
    static final String DATABASE_URL = "jdbc:mysql://localhost/books";

    // launch the application
    public static void main( String args[] )
    {
        Connection connection = null; // manages connection
        Statement statement = null; // query statement
        ResultSet resultSet = null; // manages results

        // connect to database books and query database
        try
        {
            // establish connection to database
            connection = DriverManager.getConnection(DATABASE_URL, "deitel", "deitel");

            // create Statement for querying database
            statement = connection.createStatement();

            // query database
            resultSet = statement.executeQuery("SELECT AuthorID, FirstName, LastName FROM Authors");

            ResultSetMetaData metaData = resultSet.getMetaData();
            int numberOfColumns = metaData.getColumnCount();

            System.out.print( "Authors Table of Books Database:\n" );

            for ( int i = 1; i <= numberOfColumns; i++ )
                System.out.printf("%-8s	", metaData.getColumnName(i));
            System.out.println();

            while ( resultSet.next() )
            {
                for ( int i = 1; i <= numberOfColumns; i++ )
                    System.out.printf("%-8s	", resultSet.getObject(i));
                System.out.println();
            } // end while
        } // end try
        catch ( SQLException sqlException )
        {
            sqlException.printStackTrace();
        } // end catch
        finally // ensure resultSet, statement and connection are closed
        {
            try
            {
                resultSet.close();
                statement.close();
                connection.close();
            } // end try
        }
    }
}
Chapter 28  Accessing Databases with JDBC

Lines 3–8 import the JDBC interfaces and classes from package java.sql used in this program. Line 13 declares a string constant for the database URL. This identifies the name of the database to connect to, as well as information about the protocol used by the JDBC driver (discussed shortly). Method main (lines 16–69) connects to the books database, queries the database, displays the result of the query and closes the database connection.

In past versions of Java, programs were required to load an appropriate database drive before connecting to a database. JDBC 4.0, part of Java SE 6, supports automatic driver discovery—you are no longer required to load the database driver in advance. To ensure that the program can locate the database driver class, you must include the class’s location in the program’s classpath when you execute the program. For MySQL, you include the file mysql-connector-java-5.1.7-bin.jar (in the C:\mysql-connector-java-5.1.7 directory) in your program’s classpath, as in:

```
java -classpath .;c:\mysql-connector-java-5.1.7\mysql-connector-java-5.1.7-bin.jar DisplayAuthors
```

Fig. 28.23 | Displaying the contents of the Authors table. (Part 3 of 3.)

Lines 3–8 import the JDBC interfaces and classes from package java.sql used in this program. Line 13 declares a string constant for the database URL. This identifies the name of the database to connect to, as well as information about the protocol used by the JDBC driver (discussed shortly). ```
java DisplayAuthors
```
to replace the username (second argument) and password (third argument) passed to method `getConnection` in line 27. The URL locates the database (possibly on a network or in the local file system of the computer). The URL `jdbc:mysql://localhost/books` specifies the protocol for communication (`jdbc`), the subprotocol for communication (`mysql`) and the location of the database (`//localhost/books`, where `localhost` is the host running the MySQL server and `books` is the database name). The subprotocol `mysql` indicates that the program uses a MySQL-specific subprotocol to connect to the MySQL database. If the `DriverManager` cannot connect to the database, method `getConnection` throws a `SQLException` (package `java.sql`). Figure 28.24 lists the JDBC driver names and database URL formats of several popular RDBMSs.

<table>
<thead>
<tr>
<th>RDBMS</th>
<th>Database URL format</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td><code>jdbc:mysql://hostname:portNumber/databaseName</code></td>
</tr>
<tr>
<td>ORACLE</td>
<td><code>jdbc:oracle:thin:@hostname:portNumber:databaseName</code></td>
</tr>
<tr>

<td><code>jdbc:db2:hostname:portNumber/databaseName</code></td>
</tr>
<tr>
<td>Java DB/Apache</td>
<td><code>jdbc:derby:databaseName</code> (embedded)</td>
</tr>
<tr>
<td>Derby</td>
<td><code>jdbc:derby://hostname:portNumber/databaseName</code> (network)</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td><code>jdbc:sqlserver://hostname:portNumber;databaseName=dataBaseName</code></td>
</tr>
<tr>
<td>Sybase</td>
<td><code>jdbc:sybase:Tds:hostname:portNumber/databaseName</code></td>
</tr>
</tbody>
</table>

**Fig. 28.24** | Popular JDBC database URL formats.

**Software Engineering Observation 28.5**
Most database management systems require the user to log in before accessing the database contents. `DriverManager` method `getConnection` is overloaded with versions that enable the program to supply the user name and password to gain access.

Line 30 invokes `Connection` method `createStatement` to obtain an object that implements interface `Statement` (package `java.sql`). The program uses the `Statement` object to submit SQL statements to the database.

Lines 33–34 use the `Statement` object’s `executeQuery` method to submit a query that selects all the author information from table `Authors`. This method returns an object that implements interface `ResultSet` and contains the query results. The `ResultSet` methods enable the program to manipulate the query result.

Lines 37–50 process the `ResultSet`. Line 37 obtains the metadata for the `ResultSet` as a `ResultSetMetaData` (package `java.sql`) object. The `metadata` describes the `ResultSet`’s contents. Programs can use metadata programmatically to obtain information about the `ResultSet`’s column names and types. Line 38 uses `ResultSetMetaData` method `getColumnCount` to retrieve the number of columns in the `ResultSet`. Lines 41–42 display the column names.

**Software Engineering Observation 28.6**
Metadata enables programs to process `ResultSet` contents dynamically when detailed information about the `ResultSet` is not known in advance.
Lines 45–50 display the data in each ResultSet row. First, the program positions the ResultSet cursor (which points to the row being processed) to the first row in the ResultSet with method `next` (line 45). Method next returns boolean value `true` if it is able to position to the next row; otherwise, the method returns `false`.

If there are rows in the ResultSet, lines 47–48 extract and display the contents of each column in the current row. When a ResultSet is processed, each column can be extracted as a specific Java type. In fact, ResultSetMetaData method `getColumnType` returns a constant integer from class `Types` (package `java.sql`) indicating the type of a specified column. Programs can use these values in a switch statement to invoke ResultSet methods that return the column values as appropriate Java types. If the type of a column is `Types.INTEGER`, ResultSet method `getInt` returns the column value as an `int`. ResultSet `get` methods typically receive as an argument either a column number (as an `int`) or a column name (as a `String`) indicating which column's value to obtain. Visit java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/GettingStartedTOC.fm.html for detailed mappings of SQL data types to Java types and to determine the appropriate ResultSet method to call for each SQL data type.

For simplicity, this example treats each value as an `Object`. The program retrieves each column value with ResultSet method `getObject` (line 48) and prints the `String` representation of the `Object`. Note that, unlike array indices, which start at 0, ResultSet column numbers start at 1. The `finally` block (lines 56–68) closes the ResultSet (line 60), the Statement (line 61) and the database Connection (line 62). [Note: Lines 60–62 will throw `NullPointerException` if the ResultSet, Statement or Connection objects were not created properly. For code used in industry, you should check the variables that refer to these objects to see if they’re `null` before you call `close`.]
28.8 Manipulating Databases with JDBC

28.8.2 Querying the books Database

The next example (Fig. 28.25 and Fig. 28.28) allows the user to enter any query into the program. The example displays the result of a query in a JTable, using aTableModel object to provide the ResultSet data to the JTable. A JTable is a swing GUI component that can be bound to a database to display the results of a query. Class ResultSetTableModel (Fig. 28.25) performs the connection to the database via aTableModel and maintains the ResultSet. Class DisplayQueryResults (Fig. 28.28) creates the GUI and specifies an instance of class ResultSetTableModel to provide data for the JTable.

**Common Programming Error 28.10**

A SQLException occurs if you attempt to manipulate a ResultSet after closing the Statement that created it. The ResultSet is discarded when the corresponding Statement is closed.

**Software Engineering Observation 28.7**

Each Statement object can open only one ResultSet object at a time. When a Statement returns a new ResultSet, the Statement closes the prior ResultSet. To use multiple ResultSets in parallel, separate Statement objects must return the ResultSets.

28.8 Manipulating Databases with JDBC

```java
public int getColumnCount() throws IllegalStateException {
    // ensure database connection is available
    if (!connectedToDatabase)
        throw new IllegalStateException( "Not Connected to Database" );

    // determine number of columns
    try {
        return metaData.getColumnCount();
    } // end try
    catch ( SQLException sqlException ) {
        sqlException.printStackTrace();
    } // end catch

    return 0; // if problems occur above, return 0 for number of columns
} // end method getColumnCount

public String getColumnName( int column ) throws IllegalStateException {
    // ensure database connection is available
    if (!connectedToDatabase)
        throw new IllegalStateException( "Not Connected to Database" );

    // determine column name
    try {
        return metaData.getColumnName( column + 1 );
    } // end try
    catch ( SQLException sqlException ) {
        sqlException.printStackTrace();
    } // end catch

    return ""; // if problems, return empty string for column name
} // end method getColumnName

public int getRowCount() throws IllegalStateException {
    // ensure database connection is available
    if (!connectedToDatabase)
        throw new IllegalStateException( "Not Connected to Database" );

    return numberOfRows;
} // end method getRowCount

// obtain value in particular row and column
public Object getValueAt( int row, int column ) throws IllegalStateException {

```
Chapter 28  Accessing Databases with JDBC

    // ensure database connection is available
    if (!connectedToDatabase)
        throw new IllegalStateException("Not Connected to Database");

    // obtain a value at specified ResultSet row and column
    try
    {
        return resultSet.getObject(column + 1);
    }
    catch (SQLException sqlException)
    {
        sqlException.printStackTrace();
    }
    return ""; // if problems, return empty string object

    // set new database query string
    public void setQuery(String query)
    throws SQLException, IllegalStateException
    {
        // ensure database connection is available
        if (!connectedToDatabase)
            throw new IllegalStateException("Not Connected to Database");

        // specify query and execute it
        resultSet = statement.executeQuery(query);

        // obtain meta data for ResultSet
        metaData = resultSet.getMetaData();

        // determine number of rows in ResultSet
        resultSet.last(); // move to last row
        numberOfRows = resultSet.getRow(); // get row number

        // notify JTable that model has changed
        fireTableStructureChanged();
    }

    // close Statement and Connection
    public void disconnectFromDatabase()
    {
        if (connectedToDatabase)
            try
            {
                resultSet.close();
                statement.close();
                connection.close();
            }
            catch (SQLException sqlException)
            {
            }
    }

Fig. 28.25  |  ATableModel that supplies ResultSet data to a JTable. (Part 4 of 5.)
The ResultSetTableModel constructor (lines 30–46) accepts four String arguments—the URL of the database, the username, the password and the default query to perform. The constructor throws any exceptions that occur in its body back to the application that created the ResultSetTableModel object, so that the application can determine how to handle the exception (e.g., report an error and terminate the application). Line 34 establishes a connection to the database. Lines 37–39 invoke Connection method createStatement to create a Statement object. This example uses a version of method createStatement that takes two arguments—the resultset type and the result set concurrency. The result set type (Fig. 28.26) specifies whether the ResultSet's cursor is able to scroll in both directions or forward only and whether the ResultSet is sensitive to changes made to the underlying data.

### ResultSet constants

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_FORWARD_ONLY</td>
<td>Specifies that a ResultSet's cursor can move only in the forward direction (i.e., from the first to the last row in the ResultSet).</td>
</tr>
<tr>
<td>TYPE_SCROLL_INSENSITIVE</td>
<td>Specifies that a ResultSet's cursor can scroll in either direction and that the changes made to the underlying data during ResultSet processing are not reflected in the ResultSet unless the program queries the database again.</td>
</tr>
<tr>
<td>TYPE_SCROLL_SENSITIVE</td>
<td>Specifies that a ResultSet's cursor can scroll in either direction and that the changes made to the underlying data during ResultSet processing are reflected immediately in the ResultSet.</td>
</tr>
</tbody>
</table>

### Portability Tip 28.3

Some JDBC drivers do not support scrollable ResultSets. In such cases, the driver typically returns a ResultSet in which the cursor can move only forward. For more information, see your database driver documentation.

### Common Programming Error 28.11

Attempting to move the cursor backward through a ResultSet when the database driver does not support backward scrolling causes a SQLFeatureNotSupportedException.
query that produced the ResultSet must be executed again to reflect any changes made. The result set concurrency (Fig. 28.27) specifies whether the ResultSet can be updated with ResultSet’s update methods.

<table>
<thead>
<tr>
<th>ResultSet static concurrency constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCUR_READ_ONLY</td>
<td>Specifies that a ResultSet cannot be updated (i.e., changes to the ResultSet contents cannot be reflected in the database with ResultSet’s update methods).</td>
</tr>
<tr>
<td>CONCUR_UPDATABLE</td>
<td>Specifies that a ResultSet can be updated (i.e., changes to the ResultSet contents can be reflected in the database with ResultSet’s update methods).</td>
</tr>
</tbody>
</table>

Fig. 28.27 | ResultSet constants for specifying result properties.

Portability Tip 28.4
Some JDBC drivers do not support updatable ResultSets. In such cases, the driver typically returns a read-only ResultSet. For more information, see your database driver documentation.

Common Programming Error 28.12
Attempting to update a ResultSet when the database driver does not support updatable ResultSets causes SQLFeatureNotSupportedException.

This example uses a ResultSet that is scrollable, insensitive to changes and read only. Line 45 invokes our method setQuery (lines 144–163) to perform the default query.

Method getColumnClass (lines 49–69) returns a Class object that represents the superclass of all objects in a particular column. The JTable uses this information to configure the default cell renderer and cell editor for that column in the JTable. Line 58 uses ResultSetMetaData method getColumnClassName to obtain the fully qualified class name for the specified column. Line 61 loads the class and returns the corresponding Class object. If an exception occurs, the catch in lines 63–66 prints a stack trace and line 68 returns Object.class—the Class instance that represents class Object—as the default type. [Note: Line 58 uses the argument column + 1. Like arrays, JTable row and column numbers are counted from 0. However, ResultSet row and column numbers are counted from 1. Thus, when processing ResultSet rows or columns for use in a JTable, it is necessary to add 1 to the row or column number to manipulate the appropriate ResultSet row or column.]

Method getColumnCount (lines 72–89) returns the number of columns in the model’s underlying ResultSet. Line 81 uses ResultSetMetaData method getColumnCount to obtain the number of columns in the ResultSet. If an exception occurs, the catch in lines 83–86 prints a stack trace and line 88 returns 0 as the default number of columns.

Method getColumnName (lines 92–109) returns the name of the column in the model’s underlying ResultSet. Line 101 uses ResultSetMetaData method getColumnName to obtain the column name from the ResultSet. If an exception occurs, the catch in lines 103–106 prints a stack trace and line 108 returns the empty string as the default column name.

Method `getRowCount` (lines 112–119) returns the number of rows in the model's underlying `ResultSet`. When method `setQuery` (lines 144–163) performs a query, it stores the number of rows in variable `numberOfRows`.

Method `getValueAt` (lines 122–141) returns the `Object` in a particular row and column of the model's underlying `ResultSet`. Line 132 uses `ResultSet` method `absolute` to position the `ResultSet` cursor at a specific row. Line 133 uses `ResultSet` method `get-Object` to obtain the `Object` in a specific column of the current row. If an exception occurs, the catch in lines 135–138 prints a stack trace and line 140 returns an empty string as the default value.

Method `setQuery` (lines 144–163) executes the query it receives as an argument to obtain a new `ResultSet` (line 152). Line 155 gets the `ResultSetMetaData` for the new `ResultSet`. Line 158 uses `ResultSet` method `last` to position the `ResultSet` cursor at the last row in the `ResultSet`. [Note: This can be slow if the table contains many rows.] Line 159 uses `ResultSet` method `getRow` to obtain the row number for the current row in the `ResultSet`. Line 162 invokes method `fireTableStructureChanged` (inherited from class `AbstractTableModel`) to notify any `JTable` using this `ResultSetTableModel` object as its model that the structure of the model has changed. This causes the `JTable` to repopulate its rows and columns with the new `ResultSet` data. Method `setQuery` throws any exceptions that occur in its body back to the application that invoked `setQuery`.

Method `disconnectFromDatabase` (lines 166–186) implements an appropriate termination method for class `ResultSetTableModel`. A class designer should provide a public method that clients of the class must invoke explicitly to free resources that an object has used. In this case, method `disconnectFromDatabase` closes the `ResultSet`, `Statement` and `Connection` (lines 173–175), which are considered limited resources. Clients of the `ResultSetTableModel` class should always invoke this method when the instance of this class is no longer needed. Before releasing resources, line 168 verifies whether the connection is already terminated. If not, the method proceeds. Note that the other methods in class `ResultSetTableModel` each throw an `IllegalStateException` if `connectedToDatabase` is `false`. Method `disconnectFromDatabase` sets `connectedToDatabase` to `false` (line 183) to ensure that clients do not use an instance of `ResultSetTableModel` after that instance has already been terminated. `IllegalStateException` is an exception from the Java libraries that is appropriate for indicating this error condition.

**DisplayQueryResults Class**

Class `DisplayQueryResults` (Fig. 28.28) implements the application’s GUI and interacts with the `ResultSetTableModel` via a `JTable` object. This application also demonstrates the `JTable` sorting and filtering capabilities introduced in Java SE 6.

```java
// Fig. 28.28: DisplayQueryResults.java
// Display the contents of the Authors table in the books database.
import java.awt.BorderLayout;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.awt.event.WindowAdapter;
import java.awt.event.WindowEvent;
import java.sql.SQLException;
import java.util.regex.PatternSyntaxException;
```

**Fig. 28.28** | Displays contents of the database books. (Part 1 of 6.)

90   {
91     try
92     {
93       tableModel.setQuery( queryArea.getText() );
94     } // end try
95     catch ( SQLException sqlException )
96     {
97       JOptionPane.showMessageDialog( null, sqlException.getMessage(), "Database error", JOptionPane.ERROR_MESSAGE );
98     }
99     // try to recover from invalid user query
100    // by executing default query
101    try
102    {
103      tableModel.setQuery( DEFAULT_QUERY );
104      queryArea.setText( DEFAULT_QUERY );
105    } // end try
106    catch ( SQLException sqlException2 )
107    {
108      JOptionPane.showMessageDialog( null, sqlException2.getMessage(), "Database error", JOptionPane.ERROR_MESSAGE );
109    }
110    // ensure database connection is closed
111    tableModel.disconnectFromDatabase();
112  }
113 Fig. 28.28 Displays contents of the database books. (Part 3 of 6.)
Chapter 28  Accessing Databases with JDBC

```java
System.exit(1); // terminate application

// ensure database connection is closed
tableModel.disconnectFromDatabase();

Fig. 28.28 | Displays contents of the database books. (Part 4 of 6.)

172 // dispose of window when user quits application (this overrides
173 // the default of HIDE_ON_CLOSE)
174 setDefaultCloseOperation( DISPOSE_ON_CLOSE );
175 // ensure database connection is closed when user quits application
176 addWindowListener(
177
178 new WindowAdapter()
179 {
180     // disconnect from database and exit when window has closed
181     public void windowClosed( WindowEvent event )
182     {
183         tableModel.disconnectFromDatabase();
184         System.exit( 0 );
185     } // end method windowClosed
186 } // end WindowAdapter inner class
187 } // end call to addWindowListener
188 } // end DisplayQueryResults constructor
189
190 public static void main( String args[] )
191 {
192     new DisplayQueryResults();
193 } // end main
194 } // end class DisplayQueryResults
Chapter 28  Accessing Databases with JDBC

Lines 27–29 and 32 declare the URL, username, password and default query that are passed to the ResultSetTableModel constructor to make the initial connection to the database and perform the default query. The DisplayQueryResults constructor (lines 38–189) creates a ResultSetTableModel object and the GUI for the application. Line 68 creates the JTable object and passes a ResultSetTableModel object to the JTable constructor, which then registers the JTable as a listener for TableModelEvents generated by the ResultSetTableModel.

Note that the local variables filterText (line 71) and sorter (lines 126–127) are declared final. These are both used from an event handler that is implemented as an anonymous inner class (lines 134–158). Any local variable that will be used in an anonymous inner class must be declared final; otherwise, a compilation error occurs.

Lines 85–124 register an event handler for the submitButton that the user clicks to submit a query to the database. When the user clicks the button, method actionPerformed (lines 90–122) invokes method setQuery from the class ResultSetTableModel to execute the new query (line 95). If the user's query fails (e.g., because of a syntax error in the user's input), lines 107–108 execute the default query. If the default query also fails, there could be a more serious error, so line 117 ensures that the database connection is closed and line 119 exits the program. The screen captures in Fig. 28.28 show the results of two queries. The first screen capture shows the default query that retrieves all the data from table Authors of database books. The second screen capture shows a query that selects each author's first name and last name from the Authors table and combines that information with the title and edition number from the Titles table. Try entering your own queries in the text area and clicking the Submit Query button to execute the query.

As of Java SE 6, JTables now allow users to sort rows by the data in a specific column. Lines 126–127 use the TableRowSorter class (from package javax.swing.table) to create an object that uses our ResultSetTableModel to sort rows in the JTable that displays query results. When the user clicks the title of a particular JTable column, the TableRowSorter interacts with the underlyingTableModel to reorder the rows based on the data in that column. Line 128 uses JTable method setRowSorter to specify the TableRowSorter for resultTable.

JTables can now show subsets of the data from the underlyingTableModel. This is known as filtering the data. Lines 133–159 register an event handler for the filterButton that the user clicks to filter the data. In method actionPerformed (lines 137–157), line
139 obtains the filter text. If the user did not specify filter text, line 142 uses JTable method `setRowFilter` to remove any prior filter by setting the filter to `null`. Otherwise, lines 147–148 use `setRowFilter` to specify a `RowFilter` (from package `javax.swing`) based on the user's input. Class `RowFilter` provides several methods for creating filters. The static method `regexFilter` receives a `String` containing a regular expression pattern as its argument and an optional set of indices that specify which columns to filter. If no indices are specified, then all the columns are searched. In this example, the regular expression pattern is the text the user typed. Once the filter is set, the data displayed in the JTable is updated based on the filtered `TableModel`.

Lines 177–188 register a `WindowListener` for the `windowClosed` event, which occurs when the user closes the window. Since `WindowListener`s can handle several window events, we extend class `WindowAdapter` and override only the `windowClosed` event handler.

### 28.9 RowSet Interface

In the previous examples, you learned how to query a database by explicitly establishing a `Connection` to the database, preparing a `Statement` for querying the database and executing the query. In this section, we demonstrate the `RowSet` interface, which configures the database connection and prepares query statements automatically. The interface `RowSet` provides several `set` methods that allow you to specify the properties needed to establish a connection (such as the database URL, user name and password of the database) and create a `Statement` (such as a query). `RowSet` also provides several `get` methods that return these properties.

There are two types of `RowSet` objects—connected and disconnected. A connected `RowSet` object connects to the database once and remains connected while the object is in use. A disconnected `RowSet` object connects to the database, executes a query to retrieve the data from the database and then closes the connection. A program may change the data in a disconnected `RowSet` while it is disconnected. Modified data can be updated in the database after a disconnected `RowSet` reestablishes the connection with the database.

Package `javax.sql.rowset` contains two subinterfaces of `RowSet`—`JdbcRowSet` and `CachedRowSet`. `JdbcRowSet`, a connected `RowSet`, acts as a wrapper around a `ResultSet` object and allows you to scroll through and update the rows in the `ResultSet`. Recall that by default, a `ResultSet` object is non-scrollable and read only—you must explicitly set the result set type constant to `TYPE_SCROLL_INSENSITIVE` and set the result set concurrency constant to `CONCUR_UPDATABLE` to make a `ResultSet` object scrollable and updatable. A `JdbcRowSet` object is scrollable and updatable by default. `CachedRowSet`, a disconnected `RowSet`, caches the data of a `ResultSet` in memory and disconnects from the database. Like `JdbcRowSet`, a `CachedRowSet` object is scrollable and updatable by default. A `CachedRowSet` object is also serializable, so it can be passed between Java applications through a network, such as the Internet. However, `CachedRowSet` has a limitation—the amount of data that can be stored in memory is limited. Package `javax.sql.rowset` contains three other subinterfaces of `RowSet`. For details of these interfaces, visit [java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/rowsetImpl.html](http://java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/rowsetImpl.html).

#### Portability Tip 28.5

*A RowSet can provide scrolling capability for drivers that do not support scrollable ResultSets.*

Chapter 28  Accessing Databases with JDBC

Figure 28.29 reimplements the example of Fig. 28.23 using a RowSet. Rather than establish the connection and create a Statement explicitly, Fig. 28.29 uses a JdbcRowSet object to create a Connection and a Statement automatically.

```java
// Fig. 28.29: JdbcRowSetTest.java
// Displaying the contents of the Authors table using JdbcRowSet.
public class JdbcRowSetTest
{
    // JDBC driver name and database URL
    static final String DATABASE_URL = "jdbc:mysql://localhost/books";
    static final String USERNAME = "deitel";
    static final String PASSWORD = "deitel";

    // constructor connects to database, queries database, processes results and displays results in window
    public JdbcRowSetTest()
    {
        // connect to database books and query database
        try
        {
            JdbcRowSet rowSet = new JdbcRowSetImpl(); // Sun’s JdbcRowSet implementation
            rowSet.setUrl(DATABASE_URL); // set database URL
            rowSet.setUsername(USERNAME); // set username
            rowSet.setPassword(PASSWORD); // set password
            rowSet.setCommand("SELECT * FROM Authors"); // set query
            rowSet.execute(); // execute query
            ResultSetMetaData metaData = rowSet.getMetaData();
            int numberOfColumns = metaData.getColumnCount();
            System.out.println("Authors Table of Books Database:
");
            // display rowset header
            for (int i = 1; i <= numberOfColumns; i++ )
            {
                System.out.printf("%-8s\t", metaData.getColumnName(i));
            }
            System.out.println();
            // display each row
            while (rowSet.next())
            {
                for (int i = 1; i <= numberOfColumns; i++ )
                {
                    System.out.printf("%-8s\t", rowSet.getObject(i));
                }
                System.out.println();
            }
            // close the underlying ResultSet, Statement and Connection
            rowSet.close();
        }
    }
}
```

Fig. 28.29  Displaying the Authors table using JdbcRowSet. (Part 1 of 2.)
The package `com.sun.rowset` provides Sun’s reference implementations of the interfaces in package `javax.sql.rowset`. Line 23 uses Sun’s reference implementation of the `JdbcRowSet` interface—`JdbcRowSetImpl`—to create a `JdbcRowSet` object. We used class `JdbcRowSetImpl` here to demonstrate the capability of the `JdbcRowSet` interface. Other databases may provide their own `RowSet` implementations.

Lines 24–26 set the `RowSet` properties that the `DriverManager` uses to establish a database connection. Line 24 invokes `JdbcRowSet` method `setUrl` to specify the database URL. Line 25 invokes `JdbcRowSet` method `setUsername` to specify the username. Line 26 invokes `JdbcRowSet` method `setPassword` to specify the password. Line 27 invokes `JdbcRowSet` method `setCommand` to specify the SQL query that will be used to populate the `RowSet`. Line 28 invokes `JdbcRowSet` method `execute` to execute the SQL query. Method execute performs four actions—it establishes a Connection to the database, prepares the query Statement, executes the query and stores the ResultSet returned by query. The Connection, Statement and ResultSet are encapsulated in the `JdbcRowSet` object.

The remaining code is almost identical to Fig. 28.23, except that line 31 obtains a `ResultSetMetaData` object from the `JdbcRowSet`, line 41 uses the `JdbcRowSet`’s next method to get the next row of the result and line 44 uses the `JdbcRowSet`’s `getObject` method to obtain a column’s value. Line 49 invokes `JdbcRowSet` method `close`, which closes the `RowSet`’s encapsulated `ResultSet`, `Statement` and `Connection`. In a CachedRowSet, invoking `close` also releases the resources held by that `RowSet`. Note that the output of this application is the same as that of Fig. 28.23.

### 28.10 Java DB/Apache Derby

As of JDK 6, Sun Microsystems now bundles the open-source, pure Java database Java DB (the Sun branded version of Apache Derby) with the JDK. In Section 28.11, we use Java...
Chapter 28  Accessing Databases with JDBC

DB to demonstrate PreparedStatements. Before you can execute the application in the next section, you must set up the AddressBook database in Java DB. Section 28.11 uses the embedded version of Java DB. There is also a network version that executes similarly to the MySQL DBMS introduced earlier in the chapter. For the purpose of the following steps, we assume you are running Microsoft Windows with Java installed in its default location. [Note: Mac OS X users may need to download and install Apache Derby (db.apache.org/derby/) if Java DB is not installed by default. Linux users should visit developers.sun.com/javadb/reference/docs/ and read “Getting Started with Java DB” for installation and configuration instructions.]

1. Java DB comes with several batch files to configure and run it. Before executing these batch files from a command prompt, you must set the environment variable \texttt{JAVA\_HOME} to refer to the JDK's \texttt{C:\Program Files\Java\jdk1.6.0_11} installation directory. [Note: You may need to change this based on the version of the JDK installed on your computer.]

2. Open the batch file \texttt{setEmbeddedCP.bat} (located in \texttt{C:\Program Files\Sun\JavaDB\bin}) in a text editor such as Notepad. Locate the line

\verbatim
@rem set DERBY\_INSTALL=

and change it to

\verbatim
@set DERBY\_INSTALL=C:\Program Files\Sun\JavaDB

Save your changes and close this file.

3. Open a Command Prompt and change directories to \texttt{C:\Program Files\Sun\JavaDB\bin}. Then, type \texttt{setEmbeddedCP.bat} and press Enter to set the environment variables required by Java DB.

4. An embedded Java DB database must reside in the same location as the application that manipulates the database. For this reason, change to the directory that contains the code for Figs. 28.30–28.32. This directory contains a SQL script \texttt{address.sql} that builds the AddressBook database.

5. Execute the command

\verbatim
"C:\Program Files\Sun\JavaDB\bin\ij"

\endverbatim

to start the command-line tool for interacting with Java DB. The double quotes are necessary because the path contains a space. This will display the \texttt{ij>} prompt.

6. At the \texttt{ij>} prompt type

\verbatim
connect 'jdbc:derby:AddressBook;create=true;user=deitel;password=deitel';

\endverbatim

to create the AddressBook database in the current directory. This command also creates the user \texttt{deitel} with the password \texttt{deitel} for accessing the database.

7. To create the database table and insert sample data in the database, type

\verbatim
run 'address.sql';

\endverbatim

8. To terminate the Java DB command-line tool, type

\verbatim
exit;

You are now ready to execute the AddressBook application in Section 28.11. Note that MySQL (or any other database that supports JDBC PreparedStatements) could also be used in Section 28.11.

**28.11 PreparedStatements**

Interface `PreparedStatement` enables you to create compiled SQL statements that execute more efficiently than `Statement` objects. `PreparedStatement` also can specify parameters, making them more flexible than `Statement`s. Programs can execute the same query repeatedly with different parameter values. For example, in the books database, you might want to locate all book titles for an author with a specific last name and first name, and you might want to execute that query for several authors. With a `PreparedStatement`, that query is defined as follows:

```java
PreparedStatement authorBooks = connection.prepareStatement(
    "SELECT LastName, FirstName, Title 
    FROM Authors INNER JOIN AuthorISBN 
    ON Authors.AuthorID=AuthorISBN.AuthorID 
    INNER JOIN Titles 
    ON AuthorISBN.ISBN=Titles.ISBN 
    WHERE LastName = ? AND FirstName = ?");
```

The two question marks (?) in the preceding SQL statement’s last line are placeholders for values that will be passed as part of the query to the database. Before executing a `PreparedStatement`, the program must specify the parameter values by using the `PreparedStatement` interface’s `set` methods.

For the preceding query, both parameters are strings that can be set with `PreparedStatement` method `setString` as follows:

```java
authorBooks.setString(1, "Deitel");
authorBooks.setString(2, "Paul");
```

Method `setString`’s first argument represents the parameter number being set, and the second argument is that parameter’s value. Parameter numbers are counted from 1, starting with the first question mark (?). When the program executes the preceding `PreparedStatement` with the parameter values shown here, the SQL passed to the database is

```
SELECT LastName, FirstName, Title 
FROM Authors INNER JOIN AuthorISBN 
    ON Authors.AuthorID=AuthorISBN.AuthorID 
INNER JOIN Titles 
    ON AuthorISBN.ISBN=Titles.ISBN 
WHERE LastName = 'Deitel' AND FirstName = 'Paul'
```

Method `setString` automatically escapes `String` parameter values as necessary. For example, if the last name is O’Brien, the statement

```java
authorBooks.setString(1, "O’Brien");
```

escapes the ‘ ’ character in O’Brien by replacing it with two single-quote characters.

**Performance Tip 28.2**

`PreparedStatement` are more efficient than `Statement` when executing SQL statements multiple times with different parameter values.
Chapter 28 Accessing Databases with JDBC

Interface PreparedStatement provides set methods for each supported SQL type. It is important to use the set method that is appropriate for the parameter’s SQL type in the database—SQLExceptions occur when a program attempts to convert a parameter value to an incorrect type. For a complete list of interface PreparedStatement’s set methods, see java.sun.com/javase/6/docs/api/java/sql/PreparedStatement.html.

Address Book Application that Uses PreparedStatement

We now present an address book application that enables you to browse existing entries, add new entries and search for entries with a specific last name. Our AddressBook Java DB database contains an Addresses table with the columns addressID, FirstName, LastName, Email and PhoneNumber. The column addressID is a so-called identity column. This is the SQL standard way to represent an autoincremented column. The SQL script we provide for this database uses the SQL IDENTITY keyword to mark the addressID column as an identity column. For more information on using the IDENTITY keyword and creating databases, see the Java DB Developer’s Guide at developers.sun.com/docs/javadb/10.4.2.0/devguide/derbydev.pdf.

Our address book application consists of three classes—Person (Fig. 28.30), PersonQueries (Fig. 28.31) and AddressBookDisplay (Fig. 28.32). Class Person is a simple class that represents one person in the address book. The class contains fields for the address ID, first name, last name, email address and phone number, as well as set and get methods for manipulating these fields.

```java
// Fig. 28.30: Person.java
// Person class that represents an entry in an address book.
public class Person {
    private int addressID;
    private String firstName;
    private String lastName;
    private String email;
    private String phoneNumber;

    // no-argument constructor
    public Person() {
    } // end no-argument Person constructor

    // constructor
    public Person( int id, String first, String last, String emailAddress, String phone ) {
        setAddressID( id );
        setFirstName( first );
        setLastName( last );
        setEmail( emailAddress );
    }

    // get and set accessor methods
    public int getAddressID() { return addressID; }
    public void setAddressID( int id ) { addressID = id; }
    public String getFirstName() { return firstName; }
    public void setFirstName( String first ) { firstName = first; }
    public String getLastName() { return lastName; }
    public void setLastName( String last ) { lastName = last; }
    public String getEmail() { return email; }
    public void setEmail( String emailAddress ) { email = emailAddress; }
    public String getPhoneNumber() { return phoneNumber; }
    public void setPhoneNumber( String phone ) { phoneNumber = phone; }
}
```

28.11 PreparedStatements

```java
24    setPhoneNumber( phone );
25 } // end five-argument Person constructor

27    // sets the addressID
28    public void setAddressID( int id )
29    {
30        addressID = id;
31 } // end method setAddressID

33    // returns the addressID
34    public int getAddressID()
35    {
36        return addressID;
37 } // end method getAddressID

39    // sets the firstName
40    public void setFirstName( String first )
41    {
42        firstName = first;
43 } // end method setFirstName

47    // returns the first name
48    public String getFirstName()
49    {
50        return firstName;
51 } // end method getFirstName

54    // sets the lastName
55    public void setLastName( String last )
56    {
57        lastName = last;
58 } // end method setLastName

62    // returns the last name
63    public String getLastName()
64    {
65        return lastName;
66 } // end method getLastName

69    // sets the email address
70    public void setEmail( String emailAddress )
71    {
72        email = emailAddress;
73 } // end method setEmail

77    // returns the email address
78    public String getEmail()
79    {
80        return email;
81 } // end method getEmail

84    // sets the phone number
85    public void setPhoneNumber( String phone )
86    {
```

Fig. 28.30 | Person class that represents an entry in an AddressBook. (Part 2 of 3.)
Class PersonQueries

Class PersonQueries (Fig. 28.31) manages the address book application’s database connection and creates the PreparedStatements that the application uses to interact with the database. Lines 18–20 declare three PreparedStatement variables. The constructor (lines 23–49) connects to the database at lines 27–28.

Lines 31–32 invoke Connection method prepareStatement to create the PreparedStatement namedselectAllPeople that selects all the rows in the Addresses table. Lines 35–36 create the PreparedStatement namedselectPeopleByLastName with a parameter. This statement selects all the rows in the Addresses table that match a particular last name. Notice the ? character that is used to specify the last-name parameter. Lines 39–42 create the PreparedStatement namedinsertNewPerson with four parameters that represent the first name, last name, email address and phone number for a new entry. Again, notice the ? characters used to represent these parameters.

```java
private static final String URL = "jdbc:derby:AddressBook";
private static final String USERNAME = "deitel";
private static final String PASSWORD = "deitel";
private Connection connection = null; // manages connection
private PreparedStatement selectAllPeople = null;
private PreparedStatement selectPeopleByLastName = null;
private PreparedStatement insertNewPerson = null;

// constructor
public PersonQueries()
{

}
```

Fig. 28.31 PreparedStatements used by the Address Book application. (Part 1 of 4.)
28.11 PreparedStatements

```java
try {
    connection =
        DriverManager.getConnection( URL, USERNAME, PASSWORD );

    // create query that selects all entries in the AddressBook
    selectAllPeople =
        connection.prepareStatement( "SELECT * FROM Addresses" );

    // create query that selects entries with a specific last name
    selectPeopleByLastName = connection.prepareStatement(
        
            "SELECT * FROM Addresses WHERE LastName = ?"
    );

    // create insert that adds a new entry into the database
    insertNewPerson = connection.prepareStatement(
        "INSERT INTO Addresses " +
        "( FirstName, LastName, Email, PhoneNumber ) " +
        "VALUES ( ?, ?, ?, ? )" );
}

catch ( SQLException sqlException )
{
    sqlException.printStackTrace();
    System.exit( 1 );
}

// select all of the addresses in the database
public List< Person > getAllPeople()
{
    List< Person > results = null;
    ResultSet resultSet = null;

    try {
        // executeQuery returns ResultSet containing matching entries
        resultSet = selectAllPeople.executeQuery();
        results = new ArrayList< Person >();

        while ( resultSet.next() )
        {
            results.add( new Person(                
                resultSet.getInt( "addressID" ),
                resultSet.getString( "FirstName" ),
                resultSet.getString( "LastName" ),
                resultSet.getString( "Email" ),
                resultSet.getString( "PhoneNumber" ) ) );
        }
    }
    catch ( SQLException sqlException )
    {
        sqlException.printStackTrace();
    }

    finally
    {
```
try {
    resultSet.close();
} // end try

catch ( SQLException sqlException )
{
    sqlException.printStackTrace();
    close();
} // end catch

return results;
} // end method getAllPeople

// select person by last name
public List< Person > getPeopleByLastName( String name )
{
    List< Person > results = null;
    ResultSet resultSet = null;

    try {
        selectPeopleByLastName.setString( 1, name ); // specify last name
        // executeQuery returns ResultSet containing matching entries
        resultSet = selectPeopleByLastName.executeQuery();

        results = new ArrayList< Person >();
        while ( resultSet.next() )
        {
            results.add( new Person( resultSet.getInt("addressID"),
                                      resultSet.getString("FirstName"),
                                      resultSet.getString("LastName"),
                                      resultSet.getString("Email"),
                                      resultSet.getString("PhoneNumber") ) );
        } // end while
    } // end try

    catch ( SQLException sqlException )
    {
        sqlException.printStackTrace();
    } // end catch

    finally
    {
        try
        {
            resultSet.close();
        } // end try

        catch ( SQLException sqlException )
        {
            sqlException.printStackTrace();
            close();
        } // end catch
    } // end finally

Fig. 28.31 | PreparedStatements used by the Address Book application. (Part 3 of 4.)

28.11 PreparedStatements

Method getAllPeople (lines 52–91) executes PreparedStatement selectAllPeople (line 60) by calling method `executeQuery`, which returns a ResultSet containing the rows that match the query (in this case, all the rows in the Addresses table). Lines 61–71 place the query results in an ArrayList of Person objects, which is returned to the caller at line 90. Method getPeopleByLastName (lines 94–135) uses PreparedStatement method `setString` to set the parameter to selectPeopleByLastName (line 101). Then, line 104 executes the query and lines 106–115 place the query results in an ArrayList of Person objects. Line 134 returns the ArrayList to the caller.

Chapter 28 Accessing Databases with JDBC

Method addPerson (lines 138–161) uses PreparedStatement method setString (lines 146–149) to set the parameters for the insertNewPerson PreparedStatement. Line 152 uses PreparedStatement method executeUpdate to insert the new record. This method returns an integer indicating the number of rows that were updated (or inserted) in the database. Method close (lines 164–174) simply closes the database connection.

Class AddressBookDisplay

The AddressBookDisplay (Fig. 28.32) application uses a PersonQueries object to interact with the database. Line 59 creates the PersonQueries object. When the user presses the Browse All Entries JButton, the browseButtonActionPerformed handler (lines 309–335) is called. Line 313 calls the method getAllPeople on the PersonQueries object to obtain all the entries in the database. The user can then scroll through the entries using the Previous and Next JButtons. When the user presses the Find JButton, the queryButtonActionPerformed handler (lines 265–287) is called. Lines 267–268 call method getPeopleByLastName on the PersonQueries object to obtain the entries in the database that match the specified last name. If there are several such entries, the user can then scroll through them using the Previous and Next JButtons.

```java
import java.awt.event.ActionEvent;
import java.awt.event.ActionListener;
import java.awt.event.WindowAdapter;
import java.awt.event.WindowEvent;

// handles call when insertButton is clicked
private void insertButtonActionPerformed(ActionEvent evt)
{
    int result = personQueries.addPerson(firstNameTextField.getText(),
                                           lastNameTextField.getText(),
                                           emailTextField.getText(),
                                           phoneTextField.getText());

    if (result == 1)
        JOptionPane.showMessageDialog(this, "Person added!",
                                       "Person added", JOptionPane.PLAIN_MESSAGE);
    else
        JOptionPane.showMessageDialog(this, "Person not added!",
                                       "Error", JOptionPane.PLAIN_MESSAGE);

    browseButtonActionPerformed(evt);
} // end method insertButtonActionPerformed

// main method
public static void main(String args[])
{

Fig. 28.32 | A simple address book. (Part 7 of 8.)
To add a new entry into the AddressBook database, the user can enter the first name, last name, email and phone number (the AddressID will autoincrement) in the JTextFields and press the Insert New Entry JButton. When the user presses Insert New Entry, the insertButtonActionPerformed handler (lines 338–352) is called. Lines 340–342 call the method addPerson on the PersonQueries object to add a new entry to the database. Line

Chapter 28  Accessing Databases with JDBC

351 calls browseButtonActionPerformed to obtain the updated set of people in the address book and update the GUI accordingly.

The user can then view different entries by pressing the Previous JButton or Next JButton, which results in calls to methods previousButtonActionPerformed (lines 241–250) or nextButtonActionPerformed (lines 253–262), respectively. Alternatively, the user can enter a number in the indexTextField and press Enter to view a particular entry. This results in a call to method indexTextFieldActionPerformed (lines 290–306) to display the specified record.

28.12 Stored Procedures

Many database management systems can store individual SQL statements or sets of SQL statements in a database, so that programs accessing that database can invoke them. Such named collections of SQL statements are called stored procedures. JDBC enables programs to invoke stored procedures using objects that implement the interface CallableStatement. CallableStatements can receive arguments specified with the methods inherited from interface PreparedStatement. In addition, CallableStatements can specify output parameters in which a stored procedure can place return values. Interface CallableStatement includes methods to specify which parameters in a stored procedure are output parameters. The interface also includes methods to obtain the values of output parameters returned from a stored procedure. To learn more about CallableStatements, visit java.sun.com/javase/6/docs/technotes/guides/jdbc/getstart/callablestatement.html#999652

Portability Tip 28.6

Although the syntax for creating stored procedures differs across database management systems, the interface CallableStatement provides a uniform interface for specifying input and output parameters for stored procedures and for invoking stored procedures.

Portability Tip 28.7

According to the Java API documentation for interface CallableStatement, for maximum portability between database systems, programs should process the update counts (which indicate how many rows were updated) or ResultSets returned from a CallableStatement before obtaining the values of any output parameters.

28.13 Transaction Processing

Many database applications require guarantees that a series of database insertions, updates and deletions executes properly before the applications continue processing the next database operation. For example, when you transfer money electronically between bank accounts, several factors determine if the transaction is successful. You begin by specifying the source account and the amount you wish to transfer from that account to a destination account. Next, you specify the destination account. The bank checks the source account to determine whether its funds are sufficient to complete the transfer. If so, the bank withdraws the specified amount and, if all goes well, deposits it into the destination account to complete the transfer. What happens if the transfer fails after the bank withdraws the money from the source account? In a proper banking system, the bank redeposits the money

in the source account. How would you feel if the money was subtracted from your source account and the bank did not deposit the money in the destination account?

Transaction processing enables a program that interacts with a database to treat a database operation (or set of operations) as a single operation. Such an operation also is known as an atomic operation or a transaction. At the end of a transaction, a decision can be made either to commit the transaction or roll back the transaction. Committing the transaction finalizes the database operation(s); all insertions, updates and deletions performed as part of the transaction cannot be reversed without performing a new database operation. Rolling back the transaction leaves the database in its state prior to the database operation. This is useful when a portion of a transaction fails to complete properly. In our bank-account-transfer discussion, the transaction would be rolled back if the deposit could not be made into the destination account.

Java provides transaction processing via methods of interface Connection. Method setAutoCommit specifies whether each SQL statement commits after it completes (a true argument) or whether several SQL statements should be grouped as a transaction (a false argument). If the argument to setAutoCommit is false, the program must follow the last SQL statement in the transaction with a call to Connection method commit (to commit the changes to the database) or Connection method rollback (to return the database to its state prior to the transaction). Interface Connection also provides method getAutoCommit to determine the autocommit state for the Connection.

28.14 Wrap-Up

In this chapter, you learned basic database concepts, how to interact with data in a database using SQL and how to use JDBC to allow Java applications to manipulate MySQL and Java DB databases. You learned about the SQL commands SELECT, INSERT, UPDATE and DELETE, as well as clauses such as WHERE, ORDER BY and INNER JOIN. You learned the explicit steps for obtaining a Connection to the database, creating a Statement to interact with the database’s data, executing the statement and processing the results. Then you used a ResultSet to simplify the process of connecting to a database and creating statements. You used PreparedStatement s to create precompiled SQL statements. You also learned how to create and configure databases in both MySQL and Java DB by using predefined SQL scripts. We also provided overviews of CallableStatements and transaction processing. In the next chapter, you’ll learn about web application development with JavaServer Faces.

Summary

Section 28.1 Introduction

- A database is an integrated collection of data. A database management system (DBMS) provides mechanisms for storing, organizing, retrieving and modifying data for many users.
- Today’s most popular database management systems are relational database systems.
- SQL is the international standard language used to query and manipulate relational data.
- Programs connect to, and interact with, relational databases via an interface—software that facilitates communications between a database management system and a program.
- A JDBC driver enables Java applications to connect to a database in a particular DBMS and allows you to retrieve and manipulate database data.

Section 28.2 Relational Databases

- A relational database stores data in tables. Tables are composed of rows, and rows are composed of columns in which values are stored.
- A primary key provides a unique value that cannot be duplicated in other rows of the same table.
- Each column of a table represents a different attribute.
- The primary key can be composed of more than one column.
- Every column in a primary key must have a value, and the value of the primary key must be unique. This is known as the Rule of Entity Integrity.
- A one-to-many relationship between tables indicates that a row in one table can have many related rows in a separate table.
- A foreign key is a column in a table that must match the primary-key column in another table. This is known as the Rule of Referential Integrity.
- Foreign keys enable information from multiple tables to be joined together. There is a one-to-many relationship between a primary key and its corresponding foreign key.

Section 28.4.1 Basic SELECT Query

- The basic form of a query is

  SELECT * FROM tableName

  where the asterisk (*) indicates that all columns from tableName should be selected, and tableName specifies the table in the database from which rows will be retrieved.
- To retrieve specific columns, replace the * with a comma-separated list of column names.
Section 28.4.2 WHERE Clause

• The optional WHERE clause in a query specifies the selection criteria for the query. The basic form of a query with selection criteria is

```
SELECT columnName1, columnName2, ... FROM tableName WHERE criteria
```

• The WHERE clause can contain operators <, >, <=, >=, =, <> and LIKE. Operator LIKE is used for string pattern matching with wildcard characters percent (%) and underscore (_).

• A percent character (%) in a pattern indicates that a string matching the pattern can have zero or more characters at the percent character’s location in the pattern.

• An underscore (_) in the pattern string indicates a single character at that position in the pattern.

Section 28.4.3 ORDER BY Clause

• A query’s result can be sorted with the ORDER BY clause. The simplest form of an ORDER BY clause is

```
SELECT columnName1, columnName2, ... FROM tableName ORDER BY column ASC

SELECT columnName1, columnName2, ... FROM tableName ORDER BY column DESC
```

where ASC specifies ascending order, DESC specifies descending order and column specifies the column on which the sort is based. The default sorting order is ascending, so ASC is optional.

• Multiple columns can be used for ordering purposes with an ORDER BY clause of the form

```
ORDER BY column1 sortingOrder, column2 sortingOrder, ...
```

• The WHERE and ORDER BY clauses can be combined in one query. If used, ORDER BY must be the last clause in the query.

Section 28.4.4 Merging Data from Multiple Tables: INNER JOIN

• An INNER JOIN merges rows from two tables by matching values in columns that are common to the tables. The basic form for the INNER JOIN operator is:

```
SELECT columnName1, columnName2, ...
FROM table1
INNER JOIN table2
ON table1.columnName = table2.columnName
```

The ON clause specifies the columns from each table that are compared to determine which rows are joined. If a SQL statement uses columns with the same name from multiple tables, the column names must be fully qualified by prefixing them with their table names and a dot (.)

Section 28.4.5 INSERT Statement

• An INSERT statement inserts a new row into a table. The basic form of this statement is

```
INSERT INTO tableName (columnName1, columnName2, ..., columnNameN) VALUES (value1, value2, ..., valueN)
```

where tableName is the table in which to insert the row. The tableName is followed by a comma-separated list of column names in parentheses. The list of column names is followed by the SQL keyword VALUES and a comma-separated list of values in parentheses.

• SQL uses single quotes (‘) to delimit strings. To specify a string containing a single quote in SQL, escape the single quote with another single quote (i.e., ’’).

Section 28.4.6 UPDATE Statement

• An UPDATE statement modifies data in a table. The basic form of an UPDATE statement is

```
UPDATE tableName
SET columnName1 = value1, columnName2 = value2, ..., columnNameN = valueN
WHERE criteria
```
where tableName is the table in which to update data. The tableName is followed by keyword set and a comma-separated list of columnName = value pairs. The optional WHERE clause criteria determines which rows to update.

Section 28.4.7 DELETE Statement

• A DELETE statement removes rows from a table. The simplest form for a DELETE statement is

DELETE FROM tableName WHERE criteria

where tableName is the table from which to delete a row (or rows). The optional WHERE criteria determines which rows to delete. If this clause is omitted, all the table’s rows are deleted.

Section 28.8.1 Connecting to and Querying a Database

• Package java.sql contains classes and interfaces for accessing relational databases in Java.
• A Connection object manages the connection between a Java program and a database. Connection objects enable programs to create SQL statements that access data.
• DriverManager method getConnection attempts to connect to a database at a URL that specifies the protocol for communication, the subprotocol for communication and the database name.
• Connection method createStatement creates a Statement object, which can be used to submit SQL statements to the database.
• Statement method executeQuery executes a query and returns a ResultSet object containing the query result. ResultSet methods enable a program to manipulate query results.
• A ResultSetMetaData object describes a ResultSet’s contents. Programs can use metadata programmatically to obtain information about the ResultSet column names and types.
• ResultSetMetaData method getColumnCount retrieves the number of ResultSet columns.
• ResultSet method next positions the ResultSet cursor to the next row and returns true if the row exists; otherwise, it returns false. This method must be called to begin processing a ResultSet because the cursor is initially positioned before the first row.
• It’s possible to extract each ResultSet column as a specific Java type. ResultSetMetaData method getColumnType returns a Types constant (package java.sql) indicating the column’s type.
• ResultSet get methods typically receive as an argument either a column number (as an int) or a column name (as a String) indicating which column’s value to obtain.
• ResultSet row and column numbers start at 1.
• Each Statement object can open only one ResultSet at a time. When a Statement returns a new ResultSet, the Statement closes the prior ResultSet.
• Connection method createStatement has an overloaded version that receives the result type and the result concurrency. The result type specifies whether the ResultSet’s cursor is able to scroll in both directions or forward only and whether the ResultSet is sensitive to changes. The result concurrency specifies whether the ResultSet can be updated with ResultSet’s update methods.
• Some JDBC drivers do not support scrollable or updatable ResultSets.

Section 28.8.2 Querying the books Database

• TableModel method getColumnClass returns a Class object that represents the superclass of all objects in a particular column. A JTable uses this information to set up the default cell renderer and cell editor for that column in a JTable.
• ResultSetMetaData method getColumnClassName obtains a column’s fully qualified class name.
• TableModel method getColumnCount returns the number of columns in the underlying ResultSet.
• TableModel method getColumnName returns the column name in the underlying ResultSet.
• ResultSetMetaData method getColumnName obtains the column name from the ResultSet.
Summary

TableModel method `getRowCount` returns the number of rows in the model's ResultSet.
TableModel method `getValueAt` returns the `Object` at a particular row and column of the model's underlying ResultSet.
ResultSet method `absolute` positions the ResultSet cursor at a specific row.
AbstractTableModel method `fireTableStructureChanged` notifies any JTable using a particular TableModel object as its model that the data in the model has changed.

Section 28.9 RowSet Interface
- Interface `RowSet` configures a database connection and executes a query automatically.
- A connected RowSet remains connected to the database while the object is in use. A disconnected RowSet connects, executes a query, then closes the connection.
- `JdbcRowSet`, a connected RowSet, wraps a ResultSet object and allows you to scroll and update its rows. Unlike a ResultSet object, a JdbcRowSet object is scrollable and updatable by default.
- `CachedRowSet`, a disconnected RowSet, caches a ResultSet's data in memory. A CachedRowSet is scrollable and updatable. A CachedRowSet is also serializable.

Section 28.10 Java DB/Apache Derby
- As of JDK 6, Sun Microsystems bundles the open-source, pure Java database Java DB (the Sun branded version of Apache Derby) with the JDK.
- Java DB has both an embedded version and a network version.

Section 28.11 PreparedStatements
- PreparedStatements are compiled, so they execute more efficiently than Statements.
- PreparedStatements can have parameters, so the same query can execute with different arguments.
- A parameter is specified with a question mark (?) in the SQL statement. Before executing a PreparedStatement, you must use `PreparedStatement`'s `set` methods to specify the arguments.
- `PreparedStatement` method `setString`'s first argument represents the parameter number being set and the second argument is that parameter's value.
- Parameter numbers are counted from 1, starting with the first question mark (?).
- Method `setString` automatically escapes `String` parameter values as necessary.
- Interface `PreparedStatement` provides `set` methods for each supported SQL type.
- An identity column is the SQL standard way to represent an autoincremented column. The SQL `IDENTITY` keyword marks a column as an identity column.

Section 28.12 Stored Procedures
- JDBI enables programs to invoke stored procedures using `CallableStatement` objects.
- `CallableStatement` can specify input parameters. `CallableStatement` can specify output parameters in which a stored procedure can place return values.

Section 28.13 Transaction Processing
- Transaction processing enables a program that interacts with a database to treat a database operation (or set of operations) as a single operation—known as an atomic operation or a transaction.
- At the end of a transaction, a decision can be made to either commit or roll back the transaction.
- Committing a transaction finalizes the database operation(s)—inserts, updates and deletes cannot be reversed without performing a new database operation.
- Rolling back a transaction leaves the database in its state prior to the database operation.
- Java provides transaction processing via methods of interface `Connection`.

Chapter 28  Accessing Databases with JDBC

- Method `setAutoCommit` specifies whether each SQL statement commits after it completes (a true argument) or whether several SQL statements should be grouped as a transaction.
- When autocommit is disabled, the program must follow the last SQL statement in the transaction with a call to `Connection` method `commit` (to commit the changes to the database) or `Connection` method `rollback` (to return the database to its state prior to the transaction).
- Method `getAutoCommit` determines the autocommit state for the Connection.

**Terminology**

- SQL wildcard character `*`  
- SQL wildcard character `%`
- `JOIN` operator
- `INNER JOIN` clause
- `LIKE` operator
- `DELETE` SQL statement
- `INSERT` SQL statement
- `UPDATE` SQL statement
- `DELETE` SQL statement
- `JOIN` clause
- `ORDER BY` SQL clause
- `FOREIGN KEY`
- `JOIN` clause
- `ON` clause
- `WHERE` clause
- `IN` predicate
- `LIKE` operator
- `OR` predicate
- `NOT` predicate
- `AND` predicate
- `IS NULL`
- `IS NOT NULL`
- `IS DISTINCT FROM`
- `IS NOT DISTINCT FROM`
- `IS`
- `IS NOT`
- `IS BETWEEN`
- `IS NOT BETWEEN`
- `IN`
- `IS NOT IN`
- `EXISTS` predicate
- `NOT EXISTS` predicate
- `NOT NULL`
- `NULL`
- `IS NOT NULL`
- `IS NULL`
- `IS UNIQUE`
- `IS NOT UNIQUE`
- `IS NOT EXISTS`
- `IS EXISTS`
- `IS DISTINCT FROM`
- `IS NOT DISTINCT FROM`
- `IS NOT UNIQUE`
- `IS UNIQUE`
- `IS NOT IN`
- `IS IN`

Self-Review Exercise

28.1 Fill in the blanks in each of the following statements:

a) The international standard database language is ________.

b) A table in a database consists of ________ and ________.

c) Statement objects return SQL query results as ________ objects.

d) The ________ uniquely identifies each row in a table.

e) SQL keyword ________ is followed by the selection criteria that specify the rows to select in a query.

f) SQL keywords ________ specify the order in which rows are sorted in a query.

g) Merging rows from multiple database tables is called ________ the tables.

h) A(n) ________ is an organized collection of data.

i) A(n) ________ is a set of columns whose values match another table's primary-key values.

j) ________ method ________ is used to obtain a Connection to a database.

k) Interface ________ helps manage the connection between a Java program and a database.

l) A(n) ________ object is used to submit a query to a database.

m) Unlike a ResultSet object, ________ and ________ objects are scrollable and updatable by default.

n) ________, a disconnected RowSet, caches the data of a ResultSet in memory.

Answers to Self-Review Exercise

28.1 a) SQL. b) rows, columns. c) ResultSet. d) primary key. e) WHERE. f) ORDER BY.

g) joining. h) database. i) foreign key. j) DriverManager, getConnection. k) Connection. l) Statement.

m) JdbcRowSet, CachedRowSet. n) CachedRowSet.
Exercises

28.2 (Query Application for the books Database) Using the techniques shown in this chapter, define a complete query application for the books database. Provide the following predefined queries:

a) Select all authors from the Authors table.
b) Select a specific author and list all books for that author. Include each book’s title, year and ISBN. Order the information alphabetically by the author’s last then first name.
c) Select a specific publisher and list all books published by that publisher. Include the title, year and ISBN. Order the information alphabetically by title.
d) Provide any other queries you feel are appropriate.

Display a JComboBox with appropriate names for each predefined query. Also allow users to supply their own queries.

28.3 (Data Manipulation Application for the books Database) Define a data-manipulation application for the books database. The users should be able to edit existing data and add new data to the database (obeying referential and entity integrity constraints). Allow the user to edit the database in the following ways:

a) Add a new author.
b) Edit the existing information for an author.
c) Add a new title for an author. (Remember that the book must have an entry in the AuthorISBN table.).
d) Add a new entry in the AuthorISBN table to link authors with titles.

28.4 (Employee Database) In Section 10.7, we introduced an employee-payroll hierarchy to calculate each employee’s payroll. In this exercise, we provide a database of employees that corresponds to the employee-payroll hierarchy. (A SQL script to create the employees database is provided with the examples for this chapter.) Write an application that allows the user to:

a) Add employees to the employee table.
b) Add payroll information to the appropriate table for each new employee. For example, for a salaried employee add the payroll information to the salariedEmployees table.

Figure 28.33 is the entity-relationship diagram for the employees database.

28.5 (Employee Database Query Application) Modify Exercise 28.4 to provide a JComboBox and a JTextArea to allow the user to perform a query that is either selected from the JComboBox or defined in the JTextArea. Sample predefined queries are:

a) Select all employees working in Department SALES.
b) Select hourly employees working over 30 hours.
c) Select all commission employees in descending order of the commission rate.

28.6 (Employee Database Data Manipulation Application) Modify Exercise 28.5 to perform the following tasks:

a) Increase base salary by 10% for all base-plus-commission employees.
b) If the employee’s birthday is in the current month, add a $100 bonus.
c) For all commission employees with gross sales over $10,000, add a $100 bonus.

28.7 (AddressBook Modification: Update an Existing Entry) Modify the program in Figs. 28.30–28.32 to provide a JButton that allows the user to call a method named updatePerson in PersonQueries class to update the current entry in the AddressBook database.

28.8 (AddressBook Modification: Delete an Existing Entry) Modify the program of Exercise 28.7 to provide a JButton that allows the user to call a method named deletePerson in PersonQueries class to delete the current entry in the AddressBook database.

28.9 (ATM Case Study with a Database) Modify the ATM Case Study (Chapters 12–13) to use an actual database to store the account information. We provide a SQL script to create the Bank0a-
database, which has a single table consisting of four columns—AccountNumber (an int), PIN (an int), AvailableBalance (a double) and TotalBalance (a double).

Fig. 28.33 | Table relationships in the employees database.
